Jurassic crocodile discovery sheds light on reptiles' family tree

A A newly identified species of 150 million-year-old marine crocodile has given insights into how a group of ancient animals evolved.

The ancestor of today's crocodiles belonged to a group of animals that developed a tail fin and paddle-like limbs for life in the sea, resembling dolphins more than crocodiles. These slender animals, which fed on fast-moving prey such as squid and small fish, lived during the Jurassic era in shallow seas and lagoons in what is now Germany. Related species have previously been found in Mexico and Argentina.

B An international team of scientists, including researchers from Germany and the University of Edinburgh, identified the new species from a remarkably well-preserved skeleton. The fossil was discovered in 2014 in a quarry near the town of Bamberg in Bavaria, Germany by a team from the Naturkunde-Museum Bamberg, where it is now housed. The species, *Cricosaurus bambergensis*, takes its name from the town.

C Researchers compared the fossil with those from other museum collections, and confirmed that it was a previously unseen species. The skeleton has several distinguishing features in its jaws, the roof of its mouth and tail, some of which have not been seen in any other species.

Experts created digital images of the fossil in high resolution, to enable further research. They expect the fossil will aid greater understanding of a wider family of ancient animals, known as metriorhynchid, to which this species belonged.

D Dr Mark Young, of the University of Edinburgh's School of GeoSciences, who took part in the study, said: "The rock formations of southern Germany continue to give us fresh insights into the age of dinosaurs. These rock layers were deposited at a time when Europe was covered by a shallow sea, with countries such as Germany and the UK being a collection of islands."

E Sven Sachs, from the Naturkunde-Museum Bielefeld, who led the project, said: "The study reveals peculiar features at the palate that have not been described in any fossil crocodile so far. There are two depressions which are separated by a pronounced bar. It is not clear what these depressions were good for."

Questions 1–4

Complete each sentence with the correct ending, **A–G**, below.

Write the correct letter, **A–G**, in boxes 1–4 on your answer sheet.

- 1 The ancient species of crocodile ate marine creatures that
- 2 The skeleton is kept in
- 3 Bones of the early type of crocodile
- 4 The geology of southern Germany

- A** is believed to have lived 150 million years ago.
- B** show some unique features.
- C** resembled dolphins.
- D** was laid down when the area was under water.
- E** a museum in the town near where it was found.
- F** swam fast through the water.
- G** the University of Edinburgh's School of GeoSciences.
