

WHAT HAPPENED TO DINOSAURS?

Dinosaurs were amazing creatures that lived millions of years ago. They were big and came in all kinds of shapes, like the huge Brachiosaurus and the fast Velociraptor. Around 65 million years ago, something big happened. Maybe a giant asteroid hit the Earth, or perhaps a huge volcano erupted, covering the sky with ash, and blocking out the sun. After that, this made it too cold for plants to grow, and without plants, the dinosaurs couldn't survive. As a result, they began to disappear. Some scientists think this is what happened.

Dinosaurs lived in different ways: for example, some ate plants, while others ate meat. Some even had feathers! But when the dinosaurs disappeared, it was like opening a door for mammals, like us, to become the rulers of the planet. In the meantime, while dinosaurs are gone, their story is still super interesting and helps us learn about life a long time ago. Finally, the mystery of their extinction continues to fascinate scientists and explorers alike, so we keep searching for clues to uncover the truth.
