

Life processes of plants

Order the life processes of plants.

During photosynthesis carbon dioxide enters the leaf through the stomata and oxygen is expelled. This process is called transpiration.

This substance travels down the stem to other parts of the plant.

Photosynthesis takes place in the leaves. They use sunlight and carbon dioxide to convert raw sap into elaborated sap, that contains the nutrients for the plant.

The roots absorb water and minerals from the soil to produce raw sap.

This substance travels up the stem to the leaves.
